

**Vaccines for Adolescents ....Help keep adolescents healthy and safe with immunizations. We think this is important for you to know from the Centers for Disease Control.**

New vaccines have recently become available and are recommended for all adolescents—meningococcal and pertussis vaccines. Immunizations have the potential to protect not only the health of adolescents but their friends, families, and communities.

Administering vaccines can be easy and inexpensive when delivered as part of a preventive visit to a healthcare provider. For families with health insurance, all or most of the cost is usually covered. Lower income families may be eligible to get the vaccines at no cost through a program called Vaccines For Children (VFC). The Erie County Health Department offers free vaccine clinics, call 451-6700.

**Vaccines and the Diseases they Prevent**

Immunizations can prevent many of the diseases that pose serious threats to adolescents.

**NEW *PERTUSSIS (WHOOPIING COUGH)***

- Highly contagious with prolonged cough. If transmitted to infants, may be life-threatening
- NEW VACCINE: Tetanus-diphtheria-acellular pertussis vaccine (Tdap) adds pertussis disease protection while maintaining tetanus and diphtheria protection.
- Adolescents 11–18 years of age should receive a single shot of Tdap. Adolescents who received tetanus-diphtheria booster (Td) should receive Tdap 5 years after they received Td.

**NEW *MENINGOCOCCAL INFECTIONS***

- Extremely serious disease that can rapidly progress to meningitis, pneumonia, and death
- NEW VACCINE: Meningococcal conjugate vaccine (MCV4) provides protection against these infections.
- Adolescents should receive a single shot of this vaccine during their 11–12 year old check-up or when they enter high school or college.

**NEW *HPV (HUMAN PAPILOMAVIRUS)***

- Most common sexually transmitted virus, it is without symptoms and no available treatment
- HPV is the cause of most cervical cancers in woman
- New vaccine recommended for girls 11-12 years of age, 3 dose series

***HEPATITIS B***

- Can cause different kinds of liver disease, including cancer
- Adolescents who did not receive the hepatitis B vaccine during childhood should receive the three-shot course of this vaccine.

***VARICELLA (CHICKENPOX)***

- Highly contagious and can be a serious and sometimes life-threatening disease
- Adolescents who have not had chickenpox or the vaccine should receive this vaccine at their 11–12 year old check-up. If anyone is uncertain about having had the disease, a blood test can determine immunity.

***ADDITIONAL VACCINES***

- Some adolescents with specific health risks may need additional vaccines such as hepatitis A, influenza, and pneumococcal.
